1

Using the test function and data points, the plot looks like:

2

3

a.

b.

Show that $T_n(x) = \cos(n \cdot \arccos(x))$ is a polynomial of degree n .

1. First, we let $\theta = \arccos(x)$, and consequently $x = \cos(\theta)$, and $T_n(x) = \cos(n\theta)$.
2. Recall the identity $\cos((n+1)\theta) = 2\cos(\theta)\cos(n\theta) - \cos((n-1)\theta)$
3. Using the previous identity, and plugging in $x = \cos(\theta)$ and $T_n(x) = \cos(n\theta)$ we get $T_{n+1} = 2xT_n - T_{n-1}$

Since $T_0 = 1$, it follows by induction that the n th degree Chebyshev polynomial has degree n .

c.

Recall the trigonometric identity $\cos\left((2k+1)\frac{\pi}{2}\right) = 0$. Then to find the roots of the Chebyshev polynomial we solve

$$\cos(n \cdot \arccos(x)) = 0$$

We use the identity to find

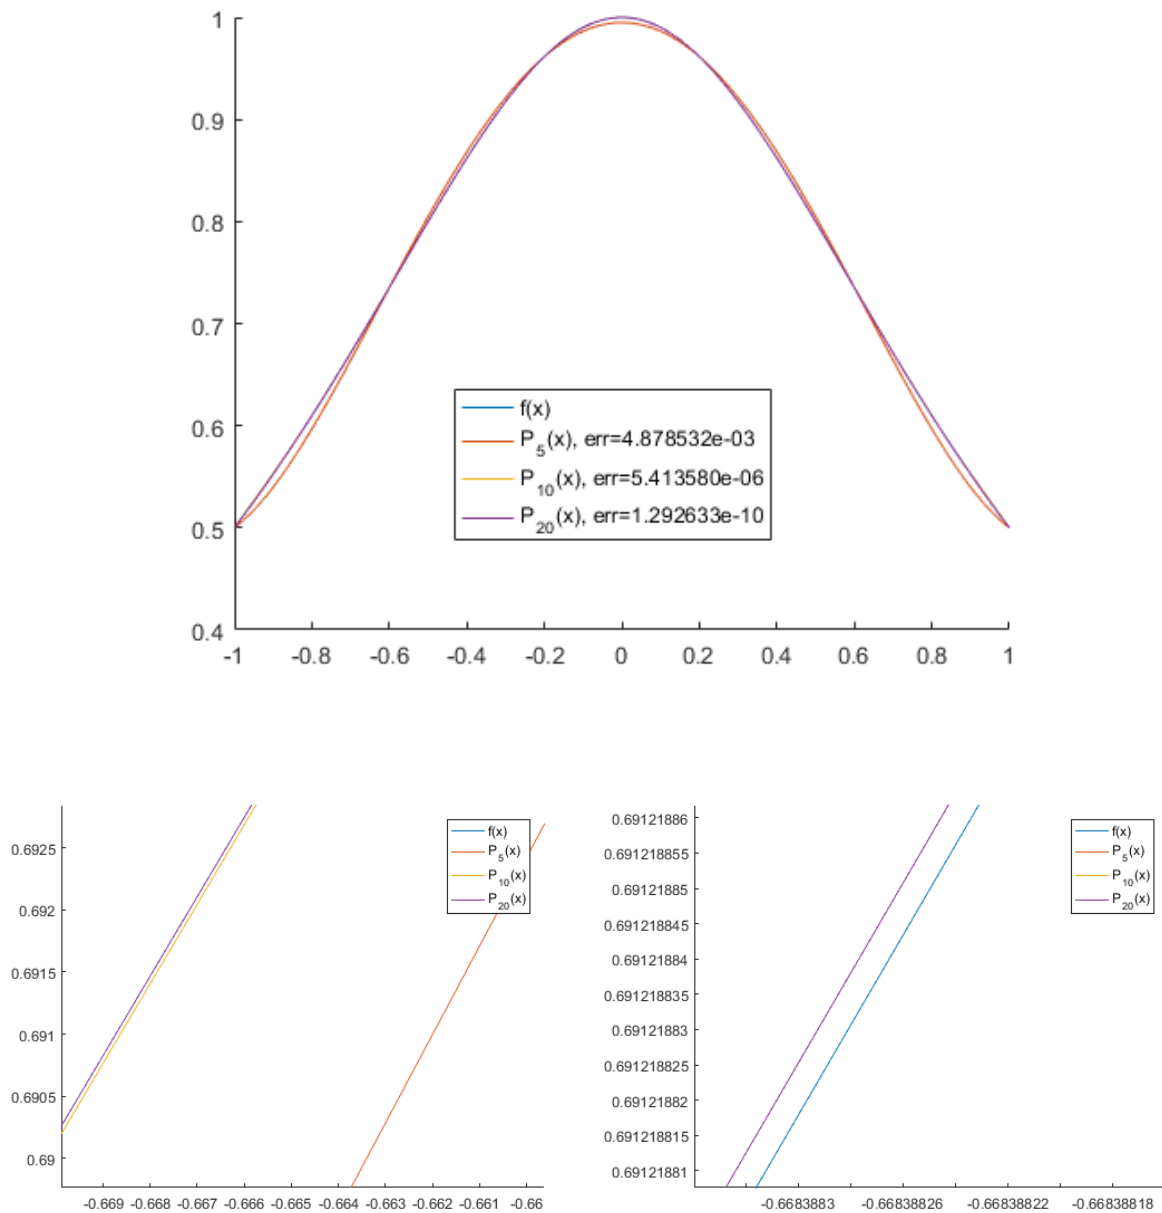

$$n \cdot \arccos(x) = (2k+1) \cdot \frac{\pi}{2}$$

then solve for x to find

$$\{\xi_i\}_{1 \leq i \leq n} = \cos\left(\frac{(2k+1)\pi}{2n}\right), \quad k = 1, \dots, n$$

4

a.

Considered on the scale from -1 to 1, even the 5th order polynomial is a fairly good approximation. As you add more points it gets even better, and the 20th order polynomial is nearly indistinguishable. The error on the main plot is the sum of squared differences.

b.

As we can see, the interpolation using the Chebyshev nodes is more accurate. The error on the plot is the sum of squared differences, and it is less than the plot in 4a.

5

When given pairwise-distinct points $\{x_0, x_1, \dots, x_n\}$, the Newton interpolation of a function is

$$f(t) \approx f[x_0] + f[x_0, x_1](t - x_0) + \dots$$

Also, we know that evaluating the interpolation at any one of the nodes gives us the correct answer. The error of the interpolation is zero at each of the nodes.

We are given an interpolating polynomial $P_n(t)$ plus the next Newton interpolation term $f[x_0, x_1, \dots, x_n, t](t - x_0) \dots (t - x_n)$. This new function that is the sum of the two is just another, better interpolation of $f(x)$, and since t is one of the nodes, we know that this function will have zero error at t . Thus

$$f(t) = P_n(t) + f[x_0, x_1, \dots, x_n, t](t - x_0)(t - x_1) \dots (t - x_n)$$
